1. Point Estimation - Chapter 7 Casella & Berger

1.1 Introduction

In the simplest case, we have n observations of data that we believe follow the same distribution.

$$X_1, \dots, X_n \stackrel{iid}{\sim} f_\theta(x)$$

where $f_\theta(x)$ is a density function involving a parameter θ . Our goal is to learn something about θ , which could be real or vector valued.

Definition 1.1.1 — Estimator. An *estimator* of θ is any function $W(X_1, \dots, X_n)$ of the data. That is, an estimator is a *statistic*.

Note:

1. $W(\mathbf{X})$ may not depend on θ .
2. $W(\mathbf{X})$ should resemble or “be close” to θ .
3. An estimator is *random*.
4. $W(X_1, \dots, X_n)$ is the estimator, $W(x_1, \dots, x_n)$ is the fixed estimate.

■ **Example 1.1** Suppose we have n observations from an exponential distribution,

$$X_1, \dots, X_n \stackrel{iid}{\sim} f_\theta(x) = \frac{1}{\theta} \exp\left\{-\frac{x}{\theta}\right\} \mathbb{1}\{x > 0\}$$

for some $\theta > 0$. The **likelihood function** is equivalent to the joint density function, expressed as a function of θ rather than the data:

$$L(\theta) = \prod_{i=1}^n \frac{1}{\theta} \exp\left\{-\frac{x_i}{\theta}\right\} = \frac{1}{\theta^n} \exp\left\{-\frac{1}{\theta} \sum_{i=1}^n x_i\right\}$$

This function represents the *likelihood* of observing the data we observed assuming the parameter was a particular value of θ . If we can maximize this function, we can determine the $\hat{\theta}$ for which the likelihood of observing \mathbf{X} was the highest. This might tell us something about the true value of θ .

To maximize $L(\theta)$, we want to take the derivative, set it equal to 0, and solve for θ . However, in many cases taking the derivative of the likelihood function will be very hard, if not impossible.

We can use the fact that taking the logarithm does not change the location of extrema. The **log-likelihood function** in this case is

$$\ell(\theta) = \log L(\theta) = -n \log \theta - \frac{1}{\theta} \sum_{i=1}^n x_i$$

Take the derivative with respect to the parameter and set equal to 0:

$$\begin{aligned} \ell'(\theta) &= -\frac{n}{\theta} + \frac{1}{\theta^2} \sum_{i=1}^n x_i \stackrel{\text{set}}{=} 0 \\ \hat{\theta} &= \frac{1}{n} \sum_{i=1}^n x_i \end{aligned}$$

Here $\hat{\theta}$ is an estimator (the sample mean). Since it maximizes $L(\theta)$, we call it the **maximum likelihood estimator** (MLE). ■

1.2 Mean Squared Error

 Read Casella & Berger Chapter 7.3 - Methods of Evaluating Estimation

Definition 1.2.1 — Mean Squared Error. If $W(\mathbf{X})$ is an estimator of θ , then the **mean squared error** (MSE) is defined as

$$E_{\theta} [(W(\mathbf{X}) - \theta)^2].$$

Definition 1.2.2 — Unbiased estimator. If $W(\mathbf{X})$ is an estimator of θ , we say that $W(\mathbf{X})$ is **unbiased** if

$$E_{\theta}[W(\mathbf{X})] = \theta \quad \forall \theta.$$

Furthermore, the **bias** of $W(\mathbf{X})$ is

$$E_{\theta}[W(\mathbf{X})] - \theta.$$

■ **Example 1.2** For $\theta > 0$, let

$$X_1, \dots, X_n \stackrel{iid}{\sim} f_{\theta}(x) = \theta x^{-2} \mathbb{1}_{\{x > \theta\}}$$

Find the MLE of θ .

$$L(\theta) = \theta^n \prod_{i=1}^n x_i^{-2} \prod_{i=1}^n \mathbb{1}_{\{x_i > \theta\}}$$

$$\hat{\theta} = \text{minimum of } x_i$$

■

Theorem 1.2.1 $\text{MSE}(W) = \text{bias}^2 + \text{Var}(W)$

Proof:

$$\begin{aligned} E[(W(\mathbf{X}) - \theta)^2] &= E[(W - E[W] + E[W] - \theta)^2] \\ &= E[(W - E[W])^2] + E[(E[W] - \theta)^2] + 2E[(W - E[W])(E[W] - \theta)] \\ &= \text{Var}(W) + \text{bias}^2(W) + 0 \end{aligned}$$

1.3 Best Unbias Estimator

What does best mean? Answer: Minimum variance.

Recall: Given an estimator $W(\underline{X})$ for θ ,

$$MSE(\theta) = E(W(\underline{X}) - \theta)^2$$

Definition 1.3.1 — Best Unbiased Estimator. An estimator W^* is a **best unbiased estimator** of $\tau(\theta)$ if it satisfies

$$E_{\theta}(W^*) = \tau(\theta)$$

for all θ and, for any other estimator W with

$$E_{\theta}(W) = \tau(\theta)$$

we have

$$\text{Var}_{\theta}(W^*) \leq \text{Var}_{\theta}(W)$$

for all θ . W^* is also called a *uniform minimum variance unbiased estimator* (UMVUE) of $\tau(\theta)$.

Main Result: Under some assumptions we can establish a lower bound on $\text{Var}(W(\underline{X}))$.

Theorem 1.3.1 — Cramer-Rao Inequality. Also: Information Inequality.

$$\text{Var}(W(\underline{X})) \geq \frac{(\Psi'(\theta))^2}{I(\theta)}$$

where, $\Psi(\theta) = E_{\theta}(W(\underline{X}))$

and, the Fisher/Expected information, $I(\theta) = E \left(\left(\frac{\delta}{\delta\theta} \log f_{\theta}(\underline{X}) \right)^2 \right)$.

Proof: Follows from Cauchy-Schwarz Inequality

$$\text{Cov}(W(\underline{x}), \frac{\delta}{\delta\theta} \log f_{\theta}(\underline{X}))^2 \leq \text{Var}(W(\underline{X})) * \text{Var}(\frac{\delta}{\delta\theta} \log f_{\theta}(\underline{X}))$$

Assumptions:

1. $I(\theta) = E_{\theta} \left(\left(\frac{\delta}{\delta\theta} \log f_{\theta}(\underline{X}) \right)^2 \right) = \text{Var} \left(\left(\frac{\delta}{\delta\theta} \log f_{\theta}(\underline{X}) \right)^2 \right)$ is well defined and $I(\theta) > 0$.
2. $E \left(\left(\frac{\delta}{\delta\theta} \log f_{\theta}(\underline{X}) \right)^2 \right) = 0$ Thus, $I(\theta)$ is just variance.
3. $E \left(W(\underline{X}) \frac{\delta}{\delta\theta} \log f_{\theta}(\underline{X}) \right)^2 = \Psi'(\theta)$

So,

$$\text{Cov}(W(\underline{x}), \frac{\delta}{\delta\theta} \log f_{\theta}(\underline{X}))^2 \leq \text{Var}(W(\underline{X})) * \text{Var}(\frac{\delta}{\delta\theta} \log f_{\theta}(\underline{X})) \simeq \text{Var}(W(\underline{X})) \geq \frac{(\Psi'(\theta))^2}{I(\theta)}$$

Exercise 1.1 Let $\underline{X} \sim \text{Poi}(\theta)$, $Y = \sum x_i$, and $Y \sim \text{Poi}(n\theta)$. What is $I(\theta)$?

$$\begin{aligned}
I(\theta) &= E \left(\left(\frac{\delta}{\delta \theta} \log f_{\theta}(\underline{X}) \right)^2 \right) \\
&= E \left(\left(\frac{\delta}{\delta \theta} \log \prod \frac{\theta^x e^{-\theta}}{x!} \right)^2 \right) \\
&= E \left(\left(\frac{\delta}{\delta \theta} \log \frac{\theta^{\sum x_i} e^{-\theta n}}{\sum x_i!} \right)^2 \right) \\
&= E \left(\frac{\delta}{\delta \theta} (-n\theta + \sum x_i \log \theta - \sum \log x_i!) \right)^2 \\
&= E \left(\left(-n + \frac{\sum x_i}{\theta} \right)^2 \right) \\
&= E \left(n^2 - 2 \left(\frac{\sum x_i}{\theta} \right) (n) + \left(\frac{\sum x_i}{\theta} \right)^2 \right) \\
&= n^2 - \frac{2n * E(\sum x_i)}{\theta} + \frac{E((\sum x_i)^2)}{\theta^2} \\
&= n^2 - \frac{2n * E(Y)}{\theta} + \frac{E(Y)^2}{\theta} \\
&= \frac{n}{\theta}
\end{aligned}$$

Note: $I(\theta)$ is equal to information in the whole sample, but sometimes it's just one sample (based on context).

If we assume (as in any exponential family):

$$E_{\theta} \left(\frac{\delta^2}{\delta \theta^2} \log f_{\theta}(\underline{x}) \right) = \frac{\delta^2}{\delta \theta^2} \int \log f_{\theta}(\underline{x}) f_{\theta}(\underline{x}) d\mathbf{x}$$

then, the observed information is

$$I(\theta) = -E_{\theta} \left(\frac{\delta^2}{\delta \theta^2} \log f_{\theta}(\underline{x}) \right)$$

■ **Example 1.3** Let $X_1 \dots X_n \stackrel{iid}{\sim} N(\mu, \sigma^2)$ Find the information based on σ^2 .
Write

$$\begin{aligned}
\ell(\mu, \sigma^2) &= \log \left(\prod (2\pi\sigma^2)^{\frac{1}{2}} \exp \left\{ \frac{-(x-\mu)^2}{2\sigma^2} \right\} \right) \\
&= \frac{-n}{2} \log(2\pi\sigma^2) + \sum \left(\frac{-(x_i - \mu)^2}{2\sigma^2} \right)
\end{aligned}$$

If we try to use the expected information:

$$I(\sigma^2) = E \left(\frac{\delta}{\delta \theta} \left(\frac{-n}{2} \log(2\pi\sigma^2) + \sum \left(\frac{-(x_i - \mu)^2}{2\sigma^2} \right) \right)^2 \right) \text{ which is a mess.}$$

However, using the observed information:

$$\begin{aligned}
 I(\sigma^2) &= \frac{-n}{2\sigma^4} + \frac{1}{\sigma^6} E\left(\sum (X_i - \mu)^2\right) \\
 &= \frac{-n}{2\sigma^4} + \frac{n\sigma^2}{\sigma^6} \\
 &= \frac{n}{2\sigma^4}
 \end{aligned}$$

■ **Example 1.4** Continued from previous example.

Define $S^2 = \frac{1}{n-1} \sum (X_i - \bar{X})^2$

Note: $\frac{n-1}{\sigma^2} S^2 \sim \chi_{n-1}^2$

Does S^2 achieve the C-R lower bound?

$$\begin{aligned}
 \text{Var}(S^2) &\geq \frac{\Psi'(\theta)}{I(\theta)} \\
 \frac{2\sigma^4}{n-1} &\geq \frac{1}{I(\theta)} \\
 &\geq \frac{2\sigma^4}{n}
 \end{aligned}$$

 Reread 7.3 and 6.2 in Casella and Berger

What would give equality? When $W(\underline{X})$ is a linear function of $\frac{\delta}{\delta\theta} \log f_\theta(\underline{X})$ which leads to...

Corollary 1.3.2 — Attainment. Let X_1, \dots, X_n be iid $f(x|\theta)$, where $f(x|\theta)$ satisfies the conditions of the Cramer-Rao Theorem. Let $L(\theta|x) = \prod f(x_i|\theta)$ denote the likelihood function. If $W(X) = W(X_1, \dots, X_n)$ is any unbiased estimator of $\tau(\theta)$, then $W(X)$ attains the Cramer-Rao Lower Bound iff

$$a(\theta) (W(x) - \tau(\theta)) = \frac{\delta}{\delta\theta} \log L(\theta|x)$$

for some function $a(\theta)$.

1.4 Lost Function Optimality

Definition 1.4.1 — Loss. $L(\theta, W(\underline{x}))$ assigns a nonnegative real value called the **loss** to our decision to estimate θ by $W(\underline{X})$. General context: Decision Theory.

Typically $L(\theta, \theta) = 0$ because nothing is lost if your decision is exactly correct.

■ **Example 1.5**

$$\begin{aligned}
 L(\theta, W(\underline{X})) &= (\theta - W(X))^2 && \text{square error loss} \\
 &= |\theta - W(X)| && \text{absolute error loss} \\
 &= \frac{W(X)}{\theta} - 1 - \log \frac{W(X)}{\theta} && \text{Stein's loss}
 \end{aligned}$$

Definition 1.4.2 — Risk. Risk of estimating θ by $W(\underline{X})$ is

$$R(\theta, W) = E(\theta, W(\underline{X}))$$

Exercise 1.2 If X_1, \dots, X_n are iid with mean μ and variance σ^2 what is

$$E\left(\sum_{i=1}^n (X_i - \bar{X})^2\right)?$$

Note:

1. $\sum i = i^n (X_i - \bar{X})^2 = \sum (X_i^2) - n\bar{X}$
2. $\text{Var}(X) = E(X^2) - E(X)^2$
3. $\text{Var}\left(\frac{X_i}{n}\right) = \frac{\sigma^2}{n^2}$
4. $\text{Var}(\bar{X}) = \frac{\sigma^2}{n}$

Thus,

$$\begin{aligned} E(\sum X_i^2) &= (\sigma^2 + \mu^2)n \\ -nE(\bar{X}^2) &= -n(\mu^2 + \frac{\sigma^2}{n}) \end{aligned}$$

We may conclude, $\frac{1}{n-1} \sum (X_i - \bar{X})^2$ is an unbiased estimator of σ^2 called S^2 . ■

Theorem 1.4.1 — Cauchy-Schwarz Inequality.

$$||\langle x, y \rangle||^2 \leq ||\langle x, x \rangle|| * ||\langle y, y \rangle||$$

In terms of $E(X)$ if A & B have $\mu = 0$:

$$(E(AB))^2 \leq E(A^2) * E(B^2)$$

Or in terms of covariance:

$$\text{Cov}^2(AB) \leq \text{Var}(A) * \text{Var}(B)$$

Proof: Let $D = B - \frac{E(AB)}{E(A^2)}A$, given $D^2 \geq 0$.

$$\begin{aligned} E(D^2) &= E(B^2 - 2(B)\left(\frac{E(AB)}{E(A^2)}A\right) + \left(\frac{E(AB)}{E(A^2)}A\right)^2) \\ &= E(B^2) - 2\left(\frac{E(AB)^2}{E(A^2)}\right) + \frac{E(AB)}{E(A^2)}E(A^2) \\ &= E(B^2) - \frac{E(AB)^2}{E(A^2)} \geq 0 \end{aligned}$$

1.5 Practice Problems

Chapter 7 Exercises (pp. 355 to 367): 7.2, 7.6, 7.7, 7.10, 7.12, 7.13, 7.14, 7.19, 7.20, 7.21, 7.22, 7.23, 7.25, 7.30, 7.37, 7.38, 7.44, 7.47, 7.48, 7.49, 7.52

Problem 1.1 (C&B 7.2) Let X_1, \dots, X_n be a random sample from a $\text{Gamma}(\alpha, \beta)$ population.

- (a) Find the MLE of β , assuming α is known.

- (b) If α and β are both unknown, there is no explicit formula for the MLEs of α and β , but the maximum can be found numerically. The result in part (a) can be used to reduce the problem to the maximization of a univariate function. Find the MLEs for α and β for the data in Exercise 7.10(c).

Solution.

(a) Gamma distribution pdf: $\frac{\beta^\alpha}{\Gamma(\alpha)} x^{\alpha-1} e^{-\beta x}$

$$L(\beta) = \frac{\beta^{n\alpha}}{\Gamma(\alpha)^n} [\prod x]^{n\alpha-1} e^{-\beta \sum x}$$

$$\ell(\beta) = n\alpha \log \beta - n \log \Gamma(\alpha) + (n\alpha - 1) \log(\prod x_i) - \beta \sum x_i$$

$$\frac{\partial \ell}{\partial \beta} = \frac{n\alpha}{\beta} - \sum x_i$$

$$\hat{\beta} = \frac{n\alpha}{\sum x_i}$$

 The density of Gamma can also be in the form with $\frac{1}{\beta}$ which would mean $\hat{\beta}$ would be $\frac{\sum x_i}{n\alpha}$.

(b) The new likelihood with $\hat{\beta}$ plugged in is:

$$L(\beta) = \frac{\left(\frac{n\alpha}{\sum x_i}\right)^{n\alpha}}{\Gamma(\alpha)^n} [\prod x]^{n\alpha-1} e^{-\left(\frac{n\alpha}{\sum x_i}\right) \sum x}$$

To solve...use a computer.

Problem 1.2 (C&B 7.6) Let X_1, \dots, X_n be a random sample from the pdf

$$f(x|\theta) = \theta x^{-2}, 0 < \theta \leq x < \infty$$

- (a) What is a sufficient statistic for θ ?
 (b) Find the MLE of θ .
 (c) Find the method of moments estimator of θ ?

Solution.

(a) Use Factorization Theorem.

$$L(\theta) = \theta^n \prod (x_i^2) \prod I\{\theta \leq x < \infty\} \text{ where } \prod I\{\theta \leq x < \infty\} = x_{(1)}$$

Thus the sufficient statistic is the minimum x .

(b) $L(\theta|x) = \theta^n \prod (x_i^2) \prod I\{\theta \leq x < \infty\}$. θ^n is increasing in θ . The second term does not involve θ . So to maximize $L(\theta|x)$, we want to make θ as large as possible. But because of the indicator function, $L(\theta|x) = 0$ if $\theta > x_{(1)}$. Thus, $\hat{\theta} = x_{(1)}$.

(c) $E(X) = \int_{\theta}^{\infty} \theta x^{-1} dx = \theta \log x|_{\theta}^{\infty} = \infty$. Thus the method of moments estimator of θ does not exist.

Problem 1.3 Let X_1, \dots, X_n be iid with one of two pdfs. If $\theta = 0$, then

$$f(x|\theta) = \begin{cases} 1, & \text{if } 0 < x < 1 \\ 0, & \text{otherwise} \end{cases}$$

$$f(x|\theta) = \begin{cases} \frac{1}{2\sqrt{x}}, & \text{if } 0 < x < 1 \\ 0, & \text{otherwise} \end{cases}$$

Find the MLE of θ .

Solution.

$$L(0|x) = \begin{cases} 1, & \text{if } 0 < x_i < 1 \\ 0, & \text{otherwise} \end{cases}$$

while if $\theta = 1$, then

$$L(1|x) = \begin{cases} \prod \frac{1}{2\sqrt{x}}, & \text{if } 0 < x_i < 1 \\ 0, & \text{otherwise} \end{cases}$$

Thus,

$$\hat{\theta}_{MLE} = \begin{cases} 1, & \text{if } \prod \frac{1}{2\sqrt{x}} \\ 0, & \text{otherwise} \end{cases}$$

2. Principles of Data Reduction

2.1 Sufficiency Principle

Definition 2.1.1 sufficient $T(X)$ is **sufficient** for θ if the distribution of $X|T(\underline{X})$ does not depend on θ .

Theorem 2.1.1 Factorization Theorem If we have $\underline{X} \sim f_{\theta}(\underline{x})$ then T is sufficient iff we can write f_{θ} as

$$g(T(x), \theta)h(x)$$

for some g and h .

■ **Example 2.1** $X_1, \dots, X_n \stackrel{iid}{\sim} \text{Bern}(\theta)$

pdf: $\theta^x(1-\theta)^{1-x}$

Joint pdf = $f_{\theta}(x) = \theta^{\sum x_i}(1-\theta)^{n-\sum x_i}$

So, $T(x) = \sum x_i$ ■

Q: What is the connection to Section 7.3?

A:

$$\begin{aligned} \text{Var}_{\theta}(W(\underline{X})) &= \text{Var}[E(W(X)|T(X))] + E[\text{Var}(W(X)|T(X))] \\ &\geq \text{Var}[E(W(X)|T(X))] \end{aligned}$$

Note: $E_{\theta}\{E_{\theta}[W(X)|T(X)]\} = E_{\theta}(W(X))$

$E_{\theta}[W(X)|T(X)]$ does not depend on θ . So this is a legitimate estimator since $T(X)$ is sufficient and its variance is smaller than any estimator with same mean.

General Idea of Sufficiency: If $T(X)$ is sufficient for θ , then all information in X about θ is captured in $T(X)$.

More technically, conditioning $T(X)$, the remaining randomness does not depend on θ .

R Know Thm 6.2.6 - Factorization Theorem

Definition 2.1.2 minimal sufficient $T(X)$ is **minimal sufficient** if $T(X)$ is sufficient

- is a function of any sufficient statistic

Note: " $T(X)$ is a function $S(X)$ " means that $S(x) = S(y)$ implies $T(x) = T(y)$.

■ **Example 2.2** $X_1, \dots, X_n \stackrel{iid}{\sim} N(\mu, \sigma^2)$. Find possible $T(\mu, \sigma^2)$.

$$\begin{aligned} f(\underline{x}) &= \prod (2\pi\sigma^2)^{-\frac{1}{2}} e^{-\frac{(x_i-\mu)^2}{2\sigma^2}} \\ &= (2\pi\sigma^2)^{-\frac{n}{2}} \exp \left\{ \frac{-\sum x_i^2 + 2\mu \sum x_i - n\mu^2}{2\sigma^2} \right\} \end{aligned}$$

Therefore our pair of sufficient statistics are $\sum x_i^2$ and $\sum x_i$. But are they minimal? ■

Theorem 2.1.2 6.2.13 $T(\underline{x}) = T(\underline{x})$ iff $\frac{f_{\theta}(\underline{x})}{f_{\theta}(\underline{y})}$ does not depend on θ , implying $T(\underline{x})$ is minimal sufficient statistic.

2.2 Exponential Families

Definition 2.2.1 Exponential Family An **exponential family** of densities is the set of densities given by

$$f_{\theta}(\underline{x}) = h(\underline{x})c(\theta) \exp \left\{ \sum w_i(\theta)t_i(\underline{x}) \right\}$$

As θ takes values in some set Θ , this equation may be rewritten as

$$f_{\underline{\eta}}(\underline{x}) = \exp \left\{ \underline{\eta}^T \underline{T}(\underline{x}) - A(\underline{\eta}) \right\} h(\underline{x}) I_B(\underline{x})$$

The latter equation is called the **canonical/natural parameterization**.

■ **Example 2.3** Deriving the canonical parameterization for a Normal distribution.

$$\begin{aligned} f_{(\mu, \sigma^2)} &= k \frac{1}{\sqrt{2\sigma^2}} \exp \left\{ \frac{-1}{2\sigma^2} (x - \mu)^2 \right\} \\ &= k \exp \left\{ \frac{1}{2\sigma^2} (-x^2) + \frac{\mu}{\sigma^2} (x) - \frac{\mu^2}{2\sigma^2} + \frac{1}{2} \log((2\sigma^2)) \right\} \\ &= k \exp \left\{ \eta_1 (-x^2) + \eta_2 (x) - \frac{\eta_2^2}{4\eta_1} - \frac{1}{2} \log \eta_1 \right\} \end{aligned}$$

$$\begin{aligned} \eta_1 &= \frac{1}{2\sigma^2} \Leftrightarrow \sigma^2 = \frac{1}{2\eta_1} \\ \eta_2 &= \frac{\mu}{\sigma^2} \Leftrightarrow \mu = \frac{\eta_2}{2\eta_1} \\ A(\underline{\eta}) &= \frac{\eta_2^2}{4\eta_1} - \frac{1}{2} \log \eta_1 \end{aligned}$$

Cool fact: The partial derivatives of $A(\eta)$ gives the expectations of T . The second partials give the covariance of T .

Observe $T(x) = (-x^2, x)$

$$\begin{aligned}
E(-x^2) &= \frac{\delta}{\delta\eta_1} A(\underline{\eta}) \\
&= \frac{-\eta_2^2}{4\eta_1^2} - \frac{1}{2\eta_1} \\
&= \frac{-\mu^2 * 4\sigma^4}{4\sigma^4} - \frac{2\sigma^2}{2} \\
&= -\mu^2 - \sigma^2
\end{aligned}$$

$$\begin{aligned}
E(x) &= \frac{\delta}{\delta\eta_2} A(\underline{\eta}) \\
&= \frac{\eta_2}{2\eta_1} \\
&= \mu
\end{aligned}$$

$$\begin{aligned}
Var(x^2) &= \frac{\delta^2}{\delta^2\eta_1} \\
&= \frac{\eta_2^2}{2\eta_1^3} + \frac{1}{2\eta_2} \\
&= 4\mu^2\sigma^2 + 2\sigma^4
\end{aligned}$$

2.2.1 Distribution Families

Poisson

$$\begin{aligned}
f_\lambda &= e^{-\lambda} \frac{\lambda^x}{x!} I\{x \in \mathbb{N}\} \\
&= \exp\{(\log \lambda)x - \lambda\} \\
\eta &= \log \lambda \\
T(\underline{x}) &= x \\
A(\eta) &= \lambda = e^{\log \lambda} = e^\eta
\end{aligned}$$

Beta

$$\begin{aligned}
f_{\alpha,\beta}(x) &= \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha)\Gamma(\beta)} x^{\alpha-1} (1-x)^{\beta-1} I\{0 < x < 1\} \\
&= \exp\{\log \Gamma(\alpha + \beta) - \log \Gamma(\alpha) - \log \Gamma(\beta) + (\alpha - 1) \log x + (\beta - 1) \log(1 - x)\} I\{0 < x < 1\} \\
\eta_1 &= \alpha - 1 \\
\eta_2 &= \beta - 1 \\
T_1(x) &= \log(x) \\
T_2(x) &= \log(1 - x) - x\beta + \alpha \log(\beta) - \log(\Gamma(\alpha))
\end{aligned}$$

Gamma

$$\begin{aligned}
f_{\alpha,\beta}(x) &= \frac{\beta^\alpha x^{\alpha-1}}{\Gamma(\alpha)} \exp\{-x\beta\} I\{x > 0\} \\
&= \exp\{(\alpha-1)\log(x) - \beta(x) + (\eta_1+1)\log(-\eta_2) + \log(\Gamma(\eta_1+1))\} \\
\eta_1 &= \alpha - 1 \\
\eta_2 &= \beta \\
T_1(x) &= \log(x) \\
T_2(x) &= x \\
A(\eta) &= (\eta_1+1)\log(-\eta_2) + \log(\Gamma(\eta_1+1))
\end{aligned}$$

Binomial

$$\begin{aligned}
f_p(x) &= \frac{n!}{x!(n-x)!} p^x (1-p)^{n-x} I\{0 \leq x \leq n\} \\
&= \binom{n}{x} \exp\left\{x \log \frac{p}{1-p} - (-n \log(1-p))\right\} \\
\eta &= \log \frac{p}{1-p} \\
T(x) &= x \\
A(\eta) &= -n \log(1-p)
\end{aligned}$$

Why is $E(T(x)) = \frac{\delta}{\delta \eta} A(\eta)$?

Notice: $e^{A(\eta)}$ must be the integral of $\exp\{\eta^T T(x) - A(\eta)\} h(x)$.

Differentiating on both sides and using the fact that for an exponential family we may switch integral and derivative, we obtain:

$$\frac{\delta}{\delta \eta} A(\eta) e^{A(\eta)} = e^{A(\eta)} \int \exp\{\eta^T T(x)\} h(x) [T(x)] e^{-A(\eta)} \quad (2.1)$$

$$= E(T(x)) \quad (2.2)$$

$$(2.3)$$

Recall, $f_\eta(x)$ must always integrate to 1!

 Read Casella & Berger Chapter 7.2

2.3 Complete Statistic

Recall, minimal statistics contain no redundant or unnecessary information. What might redundant information look like? From $T(x)$ we may construct g_1 and g_2 such that $E_\theta(g_1(T)) = E_\theta(g_2(T))$ for all θ which we want to avoid.

Definition 2.3.1 complete statistic (T) is obtained only if $g=0$ gives $E_\theta(g(T)) = 0$ for all θ .

Theorem 2.3.1 Complete and sufficient implies minimal statistics.

Theorem 2.3.2 If $f_{\theta}(\underline{x}) \exp \{ \eta^T T(x) = A(\eta) \} h(x)$ is a cononical exponential family of full rank then T is a complete and sufficient statistic.

Definition 2.3.2 Full Rank **Full rank** means

Parameter space H contains an open set

- T does not satisfy any linear constraint (i.e. the T are linearly independent).

Definition 2.3.3 Open Set Let k be dimation of η . To say that H contains an **open set** means there exists $\begin{cases} \varepsilon > 0 \\ \eta_0 \in H \end{cases}$ such that $B(\eta_0; \varepsilon) \subset H$

Theorem 2.3.3 Basu's Theorem Any complete and sufficient statistic (minimum sufficient) is independent of any ancillary statistic (that is, any statistic whose distribution does not depend on θ).

2.3.1 Sufficiency and Unbiasness

Suppose $E_{\theta}(W(X)) = \theta$ for all θ , thus $W(X)$ is unbiased. Then $\text{Var}[E(W(X)|T)] \leq \text{Var}(W(X))$. But what if T is not sufficient? Wel...then you won't get an estimator.

■ **Example 2.4** Suppose that $X \sim \text{Unif}(0, \theta)$. Find the UMVUE of $\sin \theta$.

Solution.

pdf: $f(x) = \frac{1}{b-a} = \frac{1}{\theta}$

$E(X) = \frac{\theta}{2}$

Thus $2X$ is unbiased for θ . But is $\sin(2X)$ unbiased for $\sin(\theta)$?

NO!

What about $\cos(2X)$?

$$\begin{aligned} E(\cos(2X)) &= \int_1^{\theta} \cos(2X) \frac{1}{\theta} dx \\ &= \frac{1}{\theta} \left(\frac{\sin(2X)}{2} \right) \Big|_0^{\theta} \\ &= \frac{\sin(2\theta)}{2\theta} \end{aligned}$$

No! Blarg. Let's bust out some calculus.

$$\begin{aligned} \int_0^{\theta} \text{estimator}(x) dx &= \theta \sin(\theta) \\ \text{estimator} &= \sin \theta + \theta \cos(\theta) \\ &= x \sin(x) + x \cos(x) \end{aligned}$$

■

Theorem 2.3.4 Rae-Blackwell [7.3.17] Let $W(X)$ be an estimator with $E_{\theta}(W(x)) = \tau(\theta)$. If $T(X)$ is a sufficient statistic, then an alternative, unbiased estimator of $\tau(\theta)$ whose variance is

uniformly not worse than that of $W(X)$ is

$$\phi(X) = E_{\theta}(W(X)|T(X))$$

Proof: Based on conditional arguments.

$$E(W) = E(E(W(X)|T(X)))$$

$\text{Var}(W) = \text{Var}(\text{Cond Exp}) + E(\text{Cond Var})$

Theorem 2.3.5 7.3.19 If $W(X)$ is UMVUE for $\tau(\theta)$ then it is the unique UMVUE, aka the best unbiased estimator for all θ .

Theorem 2.3.6 7.3.20 If $E_{\theta}(W(X)) = \tau(\theta)$, then $W(X)$ is UMVUE for $\tau(\theta)$ iff $W(X)$ is uncorrelated with any $S(X)$ such that $E_{\theta}(S(X)) = 0$.

Theorem 2.3.7 7.2.23 If $T(X)$ is a complete and sufficient statistic, then $\phi(T)$ is the unique UMVUE of its expectation (see Rao-Blackwell).

Definition 2.3.4 Jensen's Inequality If $h(x)$ is a convex function then

$$h(E(x)) \leq E(h(x))$$

for any random variable x .

2.4 Methods of Finding Estimators

2.4.1 Method of Moments

 Read about Satterthwait approximation

2.4.2 Maximum Likelihood Estimation

MLE makes data the most likely under the model specified. The quality of MLE depends on the quality of the model.

Invariance Principle: if $\hat{\theta}$ is MLE for θ , then $\tau(\hat{\theta})$ is MLE for $\tau(\theta)$.

Roughly speaking, MLEs enjoy a nice property called **asymptotic efficiency**. They achieve the smallest possible variance in large sample. Similar to Lower Bound of Cramer-Rao as $n \rightarrow$ infinity.

Definition 2.4.1 Score Function Suppose that throughout $X_1, \dots, X_n \sim f_{\theta}(x)$ the **score function** is $\sum \frac{\partial}{\partial \theta} \log f_{\theta}(x_i)$.

Take a first-order Taylor expansion of $\ell(\theta)$ around true value (θ).

$$\begin{aligned}
 \ell'(\hat{\theta}) &\simeq \ell'(\theta_0) + (\hat{\theta} - \theta_0)\ell''(\theta_0) \\
 \hat{\theta} - \theta_0 &\simeq [\ell''(\theta_0)^{-1}][\ell'(\hat{\theta}) - \ell'(\theta_0)] \\
 &= \left[-\frac{1}{n}\ell''(\theta_0)^{-1}\right]\left[\frac{1}{n}\ell'(\theta_0)\right] \\
 \frac{(\hat{\theta} - \theta_0)}{\sqrt{n}} &\simeq \frac{\frac{1}{\sqrt{n}}\ell'(\theta_0)}{\frac{-1}{n}\ell''(\theta_0)} \\
 \frac{1}{n}\ell'(\theta_0) &= \frac{1}{n}\sum \frac{\delta}{\delta\theta} \log f_{\theta}(x) \\
 \frac{-1}{n}\ell''(\theta_0) &= \frac{1}{n}\sum \frac{\delta^2}{\delta\theta^2} \log f_{\theta}(x)|_{\theta=\theta_0}
 \end{aligned}$$

Thus, $\sqrt{n}(\hat{\theta} - \theta_0) \sim N(0, [I(\theta_0)]^{-1})$

2.5 Major/Minorization Mini/Maximization

Ever EM Algorithm is special case of a MiMax.

EM = Expectation Maximization

 Read 7.2.4 in Casella & Berger

2.5.1 How EM Algorithms Work

- Choose a starting parameter, θ .

E-Step Construct the (minimizing) function.

- Maximize this function of θ . The maximizer will be next value of θ . Call it θ_1 .
- Return to (b) as long as we haven't converged.

Given μ_0 we find after one EM iteration that

$$\begin{aligned}
 \mu_1 &= \frac{\sum Y_i}{n} + \mu_0\left(1 - \frac{\mu}{n}\right) \\
 &= \mu_0\left(1 - \frac{\mu}{n}\right) + \frac{\sum Y_i}{\mu}\left(\frac{\mu}{n}\right)
 \end{aligned}$$

Thus, μ_1 always takes us $\frac{\mu}{n}$ of the way to the final answer at each iteration. This type of convergence is called **linear convergence**, which is a characteristic of EM algorithms. The linear rate of convergence is governed by "amount of missingness" and is considered slow compared to other similar methods (e.g. Newton-Raphson is optimization method that enjoys quadratic convergence). However, EM algorithms tend to trade more iterations for simpler iterations.

Suppose we wish to maximize a function that is a product of sums or integrals. Taking the log gives a sum of logs of sums/integrals:

$$\sum^A \log \sum^B s_{ab}(\theta)$$

To simplify, ignore the summation over A and take $f(\theta) = \log \sum s_{ab}(\theta)$. Fix a θ_0 . Define

$$W_{ob} \equiv \frac{S_b(\theta_0)}{\sum_{c_a}^c S(\theta_0)}$$

Goal: Maximize $f(\theta) = \log \sum S_b(\theta)$ with fixed θ_0 .

Claim: Define $Q_0(\theta) \equiv \sum^B W_{ob} * \log S_b(\theta)$.

Then $f(\theta) - f(\theta_0) \geq Q_0(\theta) - Q_0(\theta_0)$.

To verify this claim, notice that Jensen's inequality says

$$E(\log(\bullet)) \geq \log E(\bullet)$$

$$\begin{aligned} Q_0(\theta) - Q_b(\theta_0) &= \sum^B W_{ob} \log\left(\frac{S_b(\theta)}{S_b(\theta_0)}\right) \\ &\leq \log \sum^B W_{ob} \frac{S_b(\theta)}{S_b(\theta_0)} \\ &\leq \log \sum^B \frac{S_b(\theta_0)}{\sum S_c(\theta_0)} \frac{S_b(\theta)}{S_b(\theta_0)} \\ f(\theta) - f(\theta_0) &= \log \frac{S_b(\theta)}{S_c(\theta_0)} \end{aligned}$$

■ **Example 2.5** $X \sim f_\theta(x) = \lambda f_{\xi_1}(x) + (1 - \lambda) f_{\xi_2}(x)$, $\theta = (\lambda, \xi)$ Intuition: To generate X according to mixture density flip coin with Heads probability of λ . If H, generate $X \sim f_{\xi_1}(x)$. If T, generate $X \sim f_{\xi_2}$.

Write down the observed data likelihood, $\ell(\lambda, p_1, p_2)$. For a sample size, n, form a mixture of Binom(m, p_1) and Binom(m, p_2).

$$\sum \log \left(\lambda \binom{m}{\xi} p_1^{\xi_1} (1 - p_1)^{m - \xi_1} + (1 - \lambda) \binom{m}{\xi_2} p_2^{\xi_2} (1 - p_2)^{m - \xi_2} \right)$$

Now implement EM algorithm. ■

Suppose that "complete data" consists of x_{obs} & x_{miss} .

Using previous notation,

$$\begin{aligned} S_b(\theta) &= P_\theta(X_{obs} = x_{obs}, X_{miss} = b) \\ &\Rightarrow \sum^B S_b(\theta) = P_\theta(X_{obs} = x_{obs}) \end{aligned}$$

$$\begin{aligned} W_{ob} &= \frac{P_{\theta_0}(X_{obs} = x_{obs}, X_{miss} = b)}{P_\theta(X_{obs} = x_{obs})} \\ &= P_{\theta_0}(X_{miss} = b | X_{obs} = x_{obs}) \end{aligned}$$

$$Q_0(\theta) = E_{\theta_0}[\log P_\theta(X_{obs} = x_{obs}, X_{miss} = b) | X_{obs} = x_{obs}]$$

2.6 Bayes Estimators

Theorem 2.6.1 Bayes' Theorem

$$\pi(\theta|x) = \frac{f(x|\theta)\pi(\theta)}{m(x)}$$

LHS: posterior density of the parameters given data. This is what we want to know. The RHS includes

- likelihood
- prior density
- marginal density of x

Proposition 2.6.2 Dave's Bayes Way posterior \propto prior*likelihood

Definition 2.6.1 Conjugate Family If the prior is chosen from a family of distributions in such a way that the posterior is also a member, then we call this family of priors a **conjugate family**.

Definition 2.6.2 Bayes Risk Recall we previously define risk as a function of a parameter and estimator - $E(\text{Loss})$. Now that θ can be random, we may define **Bayes risk** as the average risk.

$$\int R(\theta, \delta) \pi(\theta) d\theta = E(R(\theta, \delta)) = E(L(\theta, \delta(\underline{X})))$$

Definition 2.6.3 Bayes Estimator For a give loss function, we define the **Bayes estimator** as the minimizer of the Bayes Risk.

Note: if δ^* minimizes $E(L(\theta, \delta(\underline{X}))|\underline{X} = x)$ for (almost) all x then δ^* is the Bayes Estimator.

We can conclude that under square error loss, the posterior mean is the Bayes Estimator.

Wrap up: How to choose prior? Even choosing family of distribution is hard. Considering restraints and conjugacy can help.

- Use data to estimate prio parameters
- Assign priors on our priors "hyper priors". Priorception.
- Use a Jeffery's prior: reparameterize

2.6.1 Model Based Clustering

3. Hypothesis Testing

Definition 3.0.4 hypothesis testing We see that a hypothesis testing procedure is a rule that partitions the sample space into we will accept (fail to reject) H_0 as true or not.

Let's consider a simple null hypothesis, i.e. a hypothesis of the form:

$$H_0 : \theta = \theta_0$$

We will consider three different ways to determine whether $\theta_{true} = \theta_0$

1. **Wald Test** $\hat{\theta} - \theta_0$ - consider if this is large relative to the distribution. $\hat{\theta}$ should have if H_0 true. Recall, $\sqrt{n}(\hat{\theta} - \theta_0) \sim N(0, I^{-1}(\theta_0))$.
2. **Likelihood Ratio Test** Consider $\ell(\hat{\theta}) - \ell(\theta_0)$ and determine whether this is large relative to χ^2 distribution that it will approximately have under H_0 .
3. **Rao Score Test** Consider $\nabla \ell(\theta_0)$ and determine if it is too far from 0 relative to its true approximate distribution if H_0 true.
